## Biochemistry 324 Bioinformatics

## Pairwise sequence alignment

## How do we compare genes/proteins?

- When we have sequenced a genome, we try and identify the function of "unknown" genes by finding a similar gene of known function
- To do this we need to find "similar" genes
- The similarity of genes is defined by the similarity of sequences
- Sequence similarities are obtained by aligning sequences
- Homologous sequences share an evolutionary history
- Homology is qualitative, i.e. sequences are either homologous or they are not, they are not $25 \%$ homologous, for instance
- Homologous sequences have identities, degree of conservation and similarities, which are quantitative
- Identities describe the percentage of residues that are identical at corresponding positions after alignment of the sequences
- Conservation described the percentage of residues at corresponding positions that have similar physicochemical properties (i.e., polar, acidic, etc.)
- Similarity describes the conserved + identical residues at corresponding positions in the aligned sequences

## Homologies are often seen at the structural level

Protein structure is resistant to change at sequence level

$\beta$-hemoglobin chain A

## Orthologous proteins

## Orthologous proteins (or genes)

Homologous proteins that are found in different species that share a common evolutionary ancestor, and may have related functions

- Degree of similarity of myoblobin among different species

## Paralogous proteins

## Paralogous proteins (or genes)

Homologous proteins that are coded by two genes in a single genome that arose by gene duplication, followed by gene drift

- The globin gene family in humans

## Dotplots

- A dotplot is a quick way to compare two sequences
- Residues or nucleotides at the intersect of the vertical and horizontal sequences are indicated by colours to show identity, conservation, etc.
- Diagonals show identity/conservation
- The human brain is used to identify patterns in the dotplot that are interpreted as:
- Repeats
- Deletions
- Inverted repeats

## Global and local sequence alignments

- Global alignment is the optimal alignment of two or more sequences over the full length of all sequences, introducing gaps as needed to compensate for sequence length differences
- The Needleman-Wunsch ("needle") algorithm performs global alignment
- Local alignment is the optimal alignment of short, local sequence lengths without any regard for the position of the aligned sequence within the large, full sequence
- The Smith-Waterman ("water") algorithm performs local alignments
- Try the tools at http://www.ebi.ac.uk/Tools/emboss/

## "Needle"

## How do we generate a sequence alignment?

sequence 1 (length m)

- Make a matrix of size $\mathbf{m + 1} \times \mathbf{n + 1}$ for sequence 1 and 2 of lengths $\mathbf{m}$ and $\mathbf{n}$
- When comparing 2 sequences, trace a path through the matrix with one sequence along the horizontal axis, and the other sequence along the vertical axis
- At every comparison, one of 4 results are possible:
- Identical (stay on diagonal)
- Mismatch (stay on diagonal)
- Insert gap in sequence 1 (move along vertical)
- Insert gap in sequence 2 (move along horizontal)

## Four outcomes per comparison aligning 2 sequences

## How do we find the alignment?

- Step 1: make a matrix where identical residues are indicated
(a)

| a) | Sequence 2 |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | F |  | M | D | T | P | L | N E |
|  | 0 | -2 | -4 | -6 | -8 | -10 | -12-1 | -14-16 |
| F | -2 |  |  |  |  |  |  |  |
| K | -4 |  |  |  |  |  |  |  |
| H | -6 |  |  |  |  |  |  |  |
| - M | -8 |  |  |  |  |  |  |  |
| ¢ E | -10 |  |  |  |  |  |  |  |
| $\stackrel{\rightharpoonup}{\sim}$ | -12 |  |  |  |  |  |  |  |
| P | -14 |  |  |  |  |  |  |  |
| L | -16 |  |  |  |  |  |  |  |
| E | -18 |  |  |  |  |  |  |  |

Step 2: Define a scoring scheme:
Match = +1
Mismatch = -2
Gap $($ horizontal or vertical $)=-2$

- Scores are cumulative
- Since we can start with a gap in either sequence 1 or 2 , we indicate that with to top row and first column

Calculating the score as we complete the matrix

- When comparing two residues (or nucleotides) at position $i, j$ they can be:
- Identical (score $=+1$ ) or a mismatch or gap (score $=-2$ )
- We can arrive at position i,j from
- (i-1,j-1), a previous match/mismatch
- A gap in sequence 1 , ( $\mathrm{i}-1, \mathrm{j}$ ), or
- A gap in sequence 2, (i,j-1)
- We now write at position ( $\mathrm{i}, \mathrm{j}$ ) the maximum of
- (i-1,j)+gap penalty (-2)
- (i,j-1)+gap penalty (-2)
- (i-1,j-1)+score (-2 for mismatch or +1 for match)

Choose the maximum score for a position, and move right
(d)

- When comparing the first residues F,F, we have a match, i.e., value $=+1$
- We can arrive at a score
- Diagonally $0+1=+1$
- Vertically $-2-2=-4$
- Horizontally $-2-2=-4$
- The maximum score is +1
- Choose +1

- Now, proceed along the row
- You can arrive at the next block F,M:
- From a match, introducing a gap (+1-2=-1)
- From a gap, introducing a a mismatch (-2-2=-4)
- From a gap, introducing a gap ( $-4-2=-6$ )
- Maximum score $=-1$

## Fill in each row in turn

(f)

Sequence 2

|  |  | F | M | D | T | P | L | N | E |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 0 | -2 | -4 | -6 | -8 | -10-1 | -12 |  |  |
| F | -2 | +1 | -1 | -3- | -5 | $\rightarrow 7 \rightarrow$ | -9- | -11 | $1-13$ |
| K | -4 | -1 |  |  |  |  |  |  |  |
| H | -6 |  |  |  |  |  |  |  |  |
| ㄷ. M | -8 |  |  |  |  |  |  |  |  |
| ¢ E | -10 |  |  |  |  |  |  |  |  |
| 总 D | -12 |  |  |  |  |  |  |  |  |
| P | -14 |  |  |  |  |  |  |  |  |
| L | -16 |  |  |  |  |  |  |  |  |
| E | -18 |  |  |  |  |  |  |  |  |

(g) Sequence 2

- The red arrows indicate the cell from which we came, that gave the best score

## What is the optimal alignment?

(a)

Sequence 2

|  | F |  | M | D | T | P | L | N | E |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 0 | -2 | -4 | -6 | -8 | -10 | -12 |  | -16 |
| F | -2 | +1 | -1 | - | -5 | $\rightarrow 7$ |  | 11 | 13 |
| K | -4 | -1 |  |  | -5 |  |  |  | 13 |
| H | -6 | -3 | -3 | -3- |  | $\rightarrow 7$ | -9 |  | 13 |
| \% M | -8 | -5 | -2 | -4 | -5 | $\rightarrow 7$ | -9 | -1 | 13 |
| $\mathrm{E}$ | -10 | -7 | -4 |  | -6 |  | -9 | 11 | -10 |
| $\stackrel{\text { ¢ }}{\sim}$ D | -12 | -9 | -6 |  |  | $\rightarrow 7$ |  |  | -12 |
| P | -14 | -11 | -8 | -5 | -5 | -4 |  | -8 | -10 |
| L | -16 | -13 | -10 | -7 | -7 | -6 |  |  | -7 |
| E | -18 | -15 | -12 | -9 | -9 | -8 | -5 | -5 | -4 |

- Starting from the bottom right, find the continuous path tracing the red arrows
- This path is the optimal alignment for the two sequences

$$
\begin{aligned}
& \text { Sequence } 1 \text { FKHMED-PL-E } \\
& \text { Sequence } 2 \text { F--M-DTPLNE }
\end{aligned}
$$

Needleman-Wunsch is guaranteed to find the optimal alignment Example of dynamic programming - take a complex problem, break it down into smaller problems, and solve each only once, storing the result

## Smith-Waterman Algorithm (Local Alignment)

- Use RNA sequence as example here
- Construct matrix $m+1, n+1$ for $m, n$ sequences
- Method is also with dynamic programming, like "needle", but in "water" the scoring scheme is different:
- The maximum of:
- Diagonal movement: score of (i-1,j-1) + value of match/mismatch
- Horizontal movement: score of (i-1,j) + gap penalty
- Vertical movement: score of (i,j-1) + gap penalty
- If all the above $<0$, then insert the score 0

Sequence 1

Match = +3
Mismatch $=-2$
Gap $=-1$

## Smith-Waterman Algorithm (Local Alignment)

|  |  | $A$ | $A$ | U | G | C | C | A | U | U | G | A | C | G | G |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| G | 0 | 2 | 2 | 1 | 5 | 4 | 3 | 7 | 6 | 10 | 14 | 13 | 12 | 16 | 15 |

- Calculate the maximum score for each cell, keeping track of the path
- Find the maximum score in the matrix
- Trace the path back until you hit 0
- Generate your own "water" matrices with your own scores: http://fridolin-linder.com/2016/03/30/local-alignment.html

## Scoring matrices

- Once we have an alignment (global or local), how do we calculate similarity?
- Margaret Dayhoff developed a scheme to score alignments in proteins based on the frequency of substitutions observed in aligned, homologous proteins
- Mutations accepted by natural selection were referred to as point accepted mutations (PAM)
- Dayhoff looked at 1572 mutations in 71 groups of closely related proteins

## Mutability of amino acids

TABLE 3.2 Relative mutabilities of amino acids. The value of alanine is arbitrarily set to 100.

| Asn | 134 | His | 66 |
| :--- | :--- | :--- | :--- |
| Ser | 120 | Arg | 65 |
| Asp | 106 | Lys | 56 |
| Glu | 102 | Pro | 56 |
| Ala | 100 | Gly | 49 |
| Thr | 97 | Tyr | 41 |
| Ile | 96 | Phe | 41 |
| Met | 94 | Leu | 40 |
| Gln | 93 | Cys | 20 |
| Val | 74 | Trp | 18 |

- Common amino acid substitutions require a single nucleotide change;
- Eg. GAC $\rightarrow$ GAA ( $\mathrm{D} \rightarrow \mathrm{E}$ )
- The least mutable amino acids are often coded by only 1 or 2 codons
- (W, Y, C, F)
- A change of the last nucleotide of W codon changes the amino acid
- The low mutability of this amino acid means that mutations are not readily selected for

## PAM1 matrix

- Using data from accepted mutations and frequency of each amino acid in dataset, Dayhoff calculated substitution fraction (percentage change) when $1 \%$ (i.e., 1 in 100) amino acids are mutated
- $1 \%$ is indication of degree of change, not evolutionary distance (proteins evolve at different rates)
- Each column adds to $100 \%$

|  |  | Original amino acid |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

#### Abstract

AIPNPSFLAMPTNENQDNTAIPTIDPITPIVST--PVPTM------ESIVNTVANPEAST rabbit S--HPFFMAILPNKMQDKAVTPTTNTIAAVEPT--PIPTT------EPVVVSTEVIAEASP $\begin{array}{ll}\text { rabbit S--HPFFMAILPNKMQDKAVTPTTNTIAAVEPT--PIPTT-------EPVVSTEVIAEASP } \\ \text { sheep } & \text { PHPHLSFMAIPPKKDQDKTEIPAINTIASAEPTVHSTPTT------EAVVNAVDNPEASS }\end{array}$ cattle PHPHLSFMAIPPKKNQDKTEIPTINTIASGEPT--STPTT-------EAVESTVATLEDS pig human horse PRPHASFIAIPPKKNQDKTAIPAINSIATVEPT--IVPATEPIVNAEPIVNAVVTPEASS PNLHPSFIAIPPKKIQDKIIIPTINTIATVEPT--PAPAT------EPTVDSVVTPEAFS horse PCPHPSFIAIPPKKLQEITVIPKINTIATVEPT--PIPTP------EPTVNNAVIPDASS

FIGURE 3.11 Multiple sequence alignment of seven kappa caseins, representing a protein family that is relatively poorly conserved. Only a portion of the entire alignment is shown. Note that just eight columns of residues are perfectly conserved (indicated with asterisks), and gaps of varying length form part of the alignment. In several columns, there are four different aligned amino acids (arrowheads); in two instances there are five different residues (double arrowheads). The sequences were aligned with MUSCLE 3.6 (see Chapter 6) and were human (NP_005203), equine (Equus caballus; NP_001075353), pig (Sus scrofa NP_001004026), ovine (Ovis aries NP_001009378), rabbit (Oryctolagus cuniculus P 33618 ), bovine (Bos taurus NP _ 776719) and mouse (Mus musculus NP_031812).

FIGURE 3.10 Multiple sequence alignment of a portion of the glyceraldehyde 3-phosphate dehydrogenase (GAPDH) protein from 13 organisms: Homo sapiens (human), Pan troglodytes (chimpanzee), Canis lupus (dog), Mus musculus (mouse), Rattus norvegicus (rat; three variants), Gallus gallus (chicken), Drosophila melanogaster (fruit fly), Anopheles gambiae (mosquito), Caenorhabditis elegans (worm), Schizosaccharomyces pombe (fission yeast), Saccharomyces cerevisiae (baker's yeast), Kluyveromyces lactis (a fungus), and Oryza sativa (rice). Columns in the alignment having even a single amino acid change are indicated with arrowheads. The accession numbers are given in the figure. The alignment was created by searching HomoloGene at NCBI with the term gapdh.

- Change in $\kappa$-caseins is more than 1 in every 100 amino acids
- Thus, using the PAM1 matrix will not give substitution scores that match the dataset, and we may miss some related proteins because the calculated similarity is incorrect
- The PAM250 matrix represents a dataset where $\mathbf{2 5 0}$ changes have occurred over a 100 amino acid region
- The PAM250 matrix is derived by successive matrix multiplication of the PAM1 matrix with itself, $\mathbf{2 5 0}$ times

- When calculating a PAMO matrix where there are 0 mutations per 100 amino acids, a diagonal of $100 \%$ is obtained
- The PAM $\infty$ matrix converges where the percentage change for every amino acids is its relative abundance

- The PAM250 matrix is used where proteins share an identity of $\mathbf{\sim} \mathbf{2 0 \%}$
- Although one can get information on the chance of change for each different amino acid in the alignment, it is difficult to interpret the score
- Use a relatedness odds ratio to get a more interpretable value

## The relatedness odds matrix

- The relatedness odds ratio is the ratio of the chance of having a mutation $\mathrm{i} \rightarrow \mathrm{j}$ at a position $\left(\mathrm{M}_{\mathrm{ij}}\right)$, divided by the chance that residue j appears in the second sequence by chance ( $\mathrm{f}_{\mathrm{j}}$ )
- $\mathrm{R}=\frac{M_{i j}}{f_{j}}$
- For instance, PAM250 shows that a C $\rightarrow$ L substitution has a probability of 0.02
- The frequency of occurrence of $L$ is 0.085
- $R=\frac{0.02}{0.085}=0.24$, a chance less than observed by random chance
- One can also calculate the log-odds ratio:
- $\mathrm{R}=10 \times \log _{10}\left(\frac{M_{i j}}{f_{j}}\right)$
- Thus, for the $\mathrm{C} \rightarrow \mathrm{L}$ substitution, the log-odds ratio is -6.3
- Where the log-odds ratio $>0$, the occurrence is more often than by random chance
- Where the log-odds ratio < $\mathbf{0}$, the occurrence is less often than by random chance
- When calculating similarities between aligned sequences, the log-odds ratio of each position can be added (computationally less demanding)

## The PAM250 log-odds ratio matrix

$W=+17$
What does this mean?

FIGURE 3.14 Log-odds matrix for PAM250. High PAM values (e.g., PAM250) are useful for aligning very divergent sequences. A variety of algorithms for pairwise alignment, multiple sequence alignment, and database searching (e.g., BLAST) allow you to select an assortment of PAM matrices such as PAM250, PAM70, and PAM30. Adapted from NCBI, ftp://ftp.ncbi.nlm.nih.gov/blast/matrices/.

## The BLOSUM matrices

- Henikoff and Henikoff used the BLOCK database of conserved regions of proteins that are distantly related
- The BLOSUM matrices use a $\log _{2}$ scoring scheme
- BLOSUM62 used alignments of proteins that had at least $62 \%$ sequence identity
- There are also other BLOSUM matrices, eg. BLOSUM 50, BLOSUM70, BLOSUM90, based on $50 \%, 70 \%$ and $90 \%$ sequence identity
- The BLOSUM matrices are more successful at identifying more distantly related proteins
- The scores in the BLOSUM matrices are calculated from empirical, aligned protein sequences
- The scores in the PAM matrices are derived from the PAM1 matrix, with the assumption that substitution probabilities can be extrapolated

FIGURE 3.17 The BLOSUM62 scoring matrix of Henikoff and Henikoff (1992). This matrix merges all proteins in an alignment that have $62 \%$ amino acid identity or greater into one sequence. BLOSUM62 performs better than alternative BLOSUM matrices or a variety of PAM matrices at detecting distant relationships between proteins. It is therefore the default scoring matrix for most database search programs such as BLAST (Chapter 4).

## Application of the BOSUM62 matrix

(b)
